

**Question 1)****Fermats little theorem**

Let  $p$  be a prime. Then prove for every positive integer  $a$ :

$$a^p \equiv a \pmod{p}$$

**Proof:** we can use induction

**Base:**  $a = 1 \rightarrow$  for all  $p$  which  $p$  is a prime number;  $1^p \equiv 1 \pmod{p}$

**Assumption:**  $a = n \rightarrow$  for all  $p$  which  $p$  is a prime number;  $n^p \equiv n \pmod{p}$   
 $\rightarrow n^p + 1 \equiv n + 1 \pmod{p}$

**Sentence:**  $a = n + 1 \rightarrow$  for all  $p$  which  $p$  is a prime number?  $(n+1)^p \equiv n + 1 \pmod{p}$

**We know**  $(x + y)^p \equiv x^p + y^p$ :

$$(n + 1)^p \equiv n^p + 1^p \pmod{p} \equiv n^p + 1 \pmod{p} \equiv n + 1 \pmod{p} \rightarrow ? \quad (n+1)^p \equiv n + 1 \pmod{p}$$

**Question 2)****Chinese remainder theorem**

Let  $m_1$  and  $m_2$  be two positive integers that are relatively prime. Given any two integers  $a$  and  $b$ , there exists an integers  $x$  such that:

$$\begin{aligned} x &\equiv a \pmod{m_1} \\ x &\equiv b \pmod{m_2} \end{aligned}$$

Prove any two solutions of these equations are congruent to each other modulo  $m_1 m_2$ .

**Proof:**

$$x \equiv a \pmod{m_1} \rightarrow x = m_1 q + a$$

$$x \equiv b \pmod{m_2} \rightarrow x = m_2 q' + b$$

$$m_1 q + a = m_2 q' + b \rightarrow m_1 q - m_2 q' = b - a$$

Can we find such  $q$  and  $q'$  for all  $a, b, m_1$ , and  $m_2$  where  $(m_1, m_2) = 1$ ? Bezout's identity tells us 1 is a  $\mathbb{Z}$ -linear combination of  $m_1$  and  $m_2$ , and therefore every integer is a  $\mathbb{Z}$ -linear combination of  $m_1$  and  $m_2$ .

Therefore integers  $q$  and  $q'$  satisfying  $m_1 q - m_2 q' = b - a$  exist.

Uniqueness of Solution: If  $x=c$  and  $x=c'$  both satisfy

$$\begin{aligned} x &\equiv a \pmod{m_1} \\ x &\equiv b \pmod{m_2} \end{aligned}$$

Then we have  $c \equiv c' \pmod{m_1}$  and  $c \equiv c' \pmod{m_2}$ . Then  $m_1 \mid (c-c')$  and  $m_2 \mid (c-c')$ .  
 Since  $(m_1, m_2) = 1$ , the product  $m_1 m_2$  divides  $c-c'$ , which means  $c \equiv c' \pmod{m_1 m_2}$ .  
 This shows all solutions to the initial pair of congruences are the same modulo  $m_1 m_2$

### Question 3)

#### Diffie-Hellman Key Exchange

In the DHKE protocol, the private keys are chosen from the set  $\{2, \dots, p-2\}$ . Why are the values 1 and  $p-1$  are not considered?

If (prA or a) = 1  $\rightarrow A = (\alpha^a) \pmod p = \alpha \rightarrow K_{AB} = \alpha^b \pmod p = B$

If (prB or b) = 1  $\rightarrow B = (\alpha^b) \pmod p = \alpha \rightarrow K_{AB} = \alpha^a \pmod p = A$

Both A and B are not hidden and available to everyone  $\rightarrow$  these keys are not secure

If (prA or a) =  $p-1 \rightarrow A = (\alpha^{p-1}) \pmod p \rightarrow K_{AB} = (\alpha^{p-1})^b \pmod p = \alpha^{pb-b} \pmod p$   
 $= (\alpha^b)^p * (\alpha^b)^{-1} \pmod p = B^p * B^{-1} \pmod p = B^{p-1} \pmod p = 1$  (Fermats little theorem)

If (prB or b) =  $p-1 \rightarrow B = (\alpha^{p-1}) \pmod p \rightarrow K_{AB} = (\alpha^{p-1})^a \pmod p = \alpha^{pa-a} \pmod p$   
 $= (\alpha^a)^p * (\alpha^a)^{-1} \pmod p = A^p * A^{-1} \pmod p = A^{p-1} \pmod p = 1$  (Fermats little theorem)

Common Key = 1  $\rightarrow$  it is Guessable and not secure

### Question 4)

4.1. Compute the two public keys and the common key for the DHKE scheme with the parameters  $p=467, a=228, b=57$

$$A = \alpha^a \pmod{467} = 2^{228} \pmod{467} = (2^{10})^{22} * 2^8 \pmod{467} = (90)^{22} * 2^8 = (161)^{11} * 2^8 = (236)^5 * 161 * 256 = (123)^2 * 236 * 161 * 256 = 185 * 236 * 161 * 256 = 229 * 120 = 394$$

$$B = \alpha^b \pmod{467} = 2^{57} \pmod{467} = (2^{10})^5 * 2^7 \pmod{467} = (90)^5 * 2^7 = (161)^2 * 90 * 2^7 = 236 * 90 * 128 = 236 * 312 = 313$$

$$K_{AB} = \alpha^{ba} = 2^{228 * 57} \pmod{467} = 394^{57} \pmod{467} = 192^{28} * 394 \pmod{467} = 438^{14} * 394 \pmod{467} = 374^7 * 394 = 243^3 * 374 * 394 = 207 * 243 * 374 * 394 = 332 * 251 = 206$$

4.2. We now design another DHKE scheme with the same prime  $p=467$  as in problem 4.1. this time, we use the element  $\alpha=4$ . The element 4 has order 233 and generates a subgroup with 233 elements. Compute  $k_{AB}$  for:

$$a = 400, b = 134 \rightarrow$$

$$k_{AB} = 4^{400 * 134}$$

$$4^{400} \bmod 467 = (4^{10})^{40} \bmod 467 = 161^{40} \bmod 467 = (161^2)^{20} = (236^2)^{10} = (123^2)^5 = (185^2)^2 * 185 = 134^2 * 185 = 210 * 185 = 89$$

$$89^{134} \bmod 467 = (89^2)^{67} = (449^2)^{33} * 449 = (324^2)^{16} * 324 * 449 = (368^2)^8 * 324 * 449 = (461^2)^4 * 324 * 449 = (36^2)^2 * 324 * 449 = 362^2 * 324 * 449 = 284 * 324 * 449 = 17 * 449 = 161$$

$a = 167, b = 134 \rightarrow$

$$k_{AB} = 4^{167 * 134}$$

$$4^{167} \bmod 467 = (4^{10})^{16} * 4^7 \bmod 467 = 161^{16} * 39 \bmod 467 = (161^2)^8 * 39 = (236^2)^4 * 39 = (123^2)^2 * 39 = 185^2 * 39 = 134 * 39 = 89$$

$89^{134} \rightarrow$  Similar to the above calculations

4.3. Why are the session keys identical?

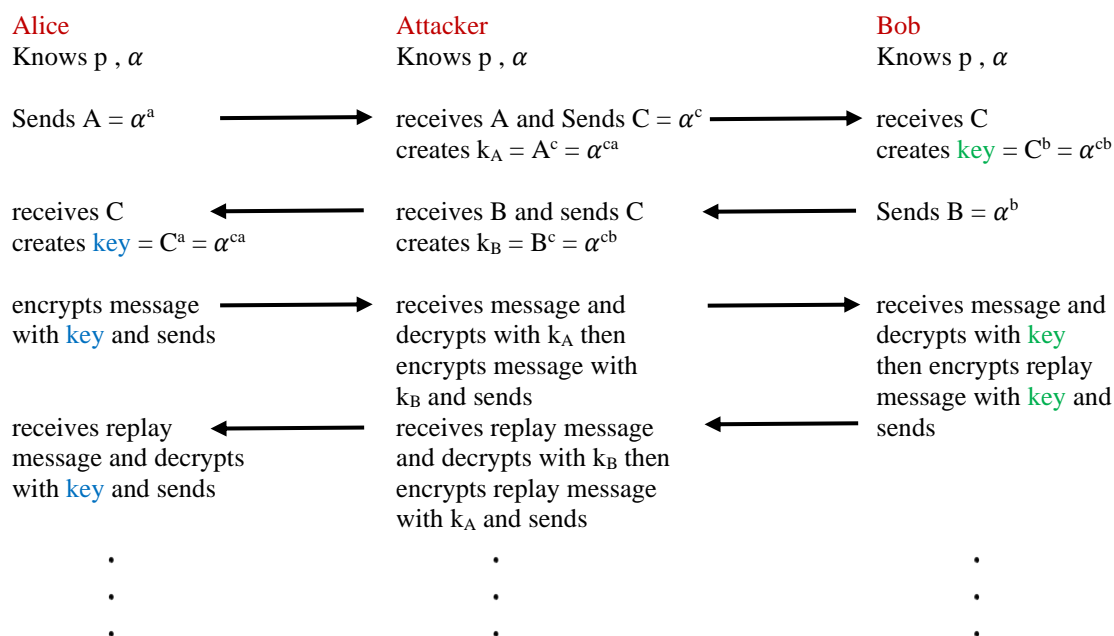

The element 4 has order 233:  $4^{233} \bmod 467 = 1$   
 $4^{167} \bmod 467 = 89$

$$4^{233} * 4^{167} \bmod 467 = 4^{400} \bmod 467 = 89 * 1 = 89 \rightarrow 4^{167} \bmod 467 = 4^{400} \bmod 467 \rightarrow$$

$$(4^{167})^{134} \bmod 467 = (4^{400})^{134} \bmod 467$$

### Question 5)

Explain Attack Man-in-the-middle to Diffie–Hellman Key Exchange.

## Question 6)

**6.1.** Find a primitive root module 11.

$$K_{11}^* = \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10\}, |K_{11}^*| = 10$$

If  $a = 2$

$2^{10} \bmod 11 = 1$	$2^5 \bmod 11 = 10$
$2^9 \bmod 11 = 6$	$2^4 \bmod 11 = 5$
$2^8 \bmod 11 = 3$	$2^3 \bmod 11 = 8$
$2^7 \bmod 11 = 7$	$2^2 \bmod 11 = 4$
$2^6 \bmod 11 = 9$	$2^1 \bmod 11 = 2$

→  $K_{11}^* = \{2^i \bmod 11 \mid 1 \leq i \leq \varphi(11)\} \rightarrow 2 \text{ is a primitive root module } 11$

**6.2.** Find a primitive root modulo  $11^2$ , modulo  $2 \cdot 11^2$ , and modulo  $11^{100}$

$\alpha \in Z_n^*$  is a generator of  $Z_n^*$  if and only if  $\alpha^{\left(\frac{\varphi(n)}{p}\right)} \not\equiv 1 \pmod{n}$  for each prime divisor  $p$  of  $\varphi(n)$

$$11^2 = 121 \rightarrow \varphi(121) = 121 * \left(1 - \frac{1}{11}\right) = 110 = 2 * 5 * 11$$

$$2^{\left(\frac{110}{2}\right)} = 2^{55} \bmod 121 = (2^{11})^5 \bmod 121 = 112^5 \bmod 121 = 81^2 * 112 \bmod 121 = 27 * 112 = 120$$

$$2^{\left(\frac{110}{5}\right)} = 2^{22} \bmod 121 = (2^{11})^2 \bmod 121 = 112^2 \bmod 121 = 81$$

$$2^{\left(\frac{110}{11}\right)} = 2^{10} \bmod 121 = 56$$

→ 2 is a primitive root module  $11^2$

$$2 \cdot 11^2 = 242 \rightarrow \varphi(242) = 242 * \left(1 - \frac{1}{11}\right) \left(1 - \frac{1}{2}\right) = 110 = 2 * 5 * 11$$

$$2^{\left(\frac{110}{2}\right)} = 2^{55} \bmod 242 = (2^{11})^5 \bmod 242 = 112^5 \bmod 242 = 202^2 * 112 \bmod 242 = 148 * 112 \bmod 242 = 120$$

$$2^{\left(\frac{110}{5}\right)} = 2^{22} \bmod 242 = (2^{11})^2 \bmod 242 = 112^2 \bmod 242 = 202$$

$$2^{\left(\frac{110}{11}\right)} = 2^{10} \bmod 242 = 56$$

→ 2 is a primitive root module  $2 \cdot 11^2$

$$11^{100} \rightarrow \varphi(11^{100}) = 11^{100} * \left(1 - \frac{1}{11}\right) = 11^{99} * 10 = 2 * 5 * 11^{99}$$

If  $a$  is a primitive root of  $p$  ( $p$  is a prime number)

then  $a$  is a primitive root of  $p^k$  if  $a^{p-1} \not\equiv 1 \pmod{p^2}$

$$2^{11-1} = 2^{10} \bmod 121 = 56$$

→ 2 is a primitive root module  $11^{100}$

### Question 7)

#### ElGamal Encryption System

If Bob uses ElGamal with  $p=44927, \alpha=7, d=22105$ , find Bob's public key, encode the message  $m=10101$ , and then decode the associated ciphertext.

**Bob calculates public\_key and sends it to Alice :**

$$\beta = \alpha^d \bmod p = 7^{22105} \bmod 44927 = 40909 \rightarrow \text{Bob\_public\_key}(p, \alpha, \beta) = (44927, 7, 40909)$$

**Alice receives Bob's public key and select a random i and calculates  $k_E$  :**

$$\text{Random } i \in \{2, 3, \dots, p-2\}, \text{ for example : } i = 2 \rightarrow \alpha^i \bmod p = 7^2 \bmod 44927 = 49 = k_E$$

**Alice calculate  $k_m$  and encrypt message with  $k_m$  and sends (cipher ,  $k_E$ ) to Bob:**

$$k_m = \beta^k \bmod p = 40909^2 \bmod 44927 = 15531$$
$$\text{cipher} = m * \beta \bmod p = 10101 * 15531 \bmod 44927 = 38474$$

**Bob receives (cipher ,  $k_E$ ) and calculates  $k_m$  and  $k_m^{-1}$  and decrypt cipher with  $k_m^{-1}$  :**

$$k_m = k_E^d \bmod p = 49^{22105} \bmod 44927 = 15531$$

if p is a prime number  $\rightarrow \varphi(p) = p - 1 \rightarrow \varphi(44927) = 44926$

$$\rightarrow k_m^{-1} = k_m^{44926-1} \bmod p = 15531^{44925} \bmod 44927 = 13888$$
$$\text{plaintext} = 38474 * k_m^{-1} \bmod p = 38474 * 13888 \bmod 44927 = 10101$$

## CrypTool:

### Question 1)

1963497163 → prime factors = 33923, 57881

### Question 2)

Three large prime numbers:

1111111111193871231

59464782315488937133

93871231564897876549

## Fermat test

The dialog box is titled "Factorization of a Number". It has two main sections. The top section, "Algorithms for factorization", lists several algorithms with checkboxes: Brute-force, Brent, Pollard, Williams, Lenstra, and Quadratic sieve. The "Input" section on the right has a text field containing "1963497163" and a button "Load number from file". Below these is a "Factorization (stepwise)" section with a "Continue" button and a "Complete factorization into primes" button. The bottom section, "Factorization", displays the result: "33923 \* 57881". It also shows "Last factorization through: Brent" and "Found 2 factors in 0.028 seconds." There is a "Details" button and a "Close" button at the bottom right.

The image shows two side-by-side screenshots of the "Prime Number Test" dialog box. Both dialogs have a title bar and a close button. The left dialog shows the "Algorithms for prime number test" section with "Fermat test" selected. The "Number or formula to test:" field contains "93871231564897876549". The "Result:" field shows a green checkmark and the same number. The right dialog shows the same interface but with the "Number or formula to test:" field containing "1111111111193871231" and the "Result:" field showing a green checkmark and the same number. Both dialogs have buttons for "Test number", "Factorize number", and "Cancel" at the bottom.

Prime Number Test

There are many methods to check if a number is prime.  
Most of these are probabilistic, meaning that they can only determine primality to a given adjustable degree of certainty.  
However, these methods are much faster than their counterpart, deterministic methods. Such methods return a 100% mathematically certain result.

## Openssl:

### Question 1)

- i. Generate a 2048bit RSA key, and save it in file named “private.key”.

```
→ ~ openssl genrsa -out private.key 2048
Generating RSA private key, 2048 bit long modulus (2 primes)
.....+++++
.....+++++
e is 65537 (0x010001)
→ ~
```

Private.key file has been attached.

- ii. Extract the public key out of the previously generated key and save it into a file named “public.key”.

```
→ ~ openssl rsa -in private.key -pubout -out public.key
writing RSA key
→ ~ cat public.key
-----BEGIN PUBLIC KEY-----
MIIBIjANBgkqhkiG9w0BAQEFAAOCAQ8AMIIBCgKCAQEAv5pzAMY39Av1WlZGuR0r
Nm46A0aI3AmUS8hh/49VuHJ6H6Ax7KvMe/lnkuIVnYcrgEaIH9ns4dvjT7jTLsI1

5QIDAQAB
-----END PUBLIC KEY-----
→ ~
```

Public.key file has been attached.

- iii. Extract all parts that contribute to the construction of the respective private key, including prime factors, private and public exponents, and so on. Save the results in a file named “structure.txt”.

```
→ ~ openssl rsa -text -in private.key > structure.txt  
writing RSA key  
→ ~
```

Structure.txt file has been attached.

Question 2)

```
→ ~ openssl s_client -connect www.feistyduck.com:443 -showcerts
```

cert.txt file has been attached.
